Introduction

Dans cette étude, nous explorons les nuances psychologiques des coureurs de trail en utilisant des techniques de clustering pour identifier des groupes homogènes au sein de cette communauté. L'objectif principal est d'analyser les profils distincts émergents au sein de cette population hétérogène, en mettant l'accent sur les caractéristiques individuelles telles que la motivation, l'anxiété, les habitudes de vie et d'autres aspects psychologiques.

À travers une approche méthodologique basée sur le clustering gaussien implémentée avec le package *mclust* en *R*, cette étude cherche à déterminer le nombre optimal de groupes représentatifs des coureurs de trail. Une fois ces groupes identifiés, nous nous pencherons sur les différences significatives entre eux, afin de mieux comprendre les dynamiques psychologiques et comportementales qui sous-tendent la passion commune du trail running.

Modélisation par clustering (mclust)

Nous avons élaboré divers modèles de mélanges afin d'explorer nos données. Pour simplifier, un modèle de mélange est un outil qui nous guide pour déceler différents groupes ou composants au sein de nos informations, ce qui peut être précieux pour dévoiler des schémas ou des tendances dissimulées. Pour choisir le modèle le plus adapté, nous avons ajusté la variable "G" de 1 à 5, en observant la meilleure valeur du BIC, nous permettant ainsi de sélectionner notre modèle optimal.

Figure 1: Comparaison des valeurs BIC pour différents modèles

Nous avons choisi le modèle de clustering avec deux groupes, car il a la meilleure valeur du BIC (Bayesian Information Criterion). Cela suggère qu'il correspond le mieux à la structure sous-jacente des données des coureurs de trail.

Attribution des clusters aux données

Voici la sortie générée par R, nous permettant d'examiner notre modèle choisi. Le code suivant a été utilisé pour créer le modèle et afficher ses caractéristiques :

```
> -----
> Gaussian finite mixture model fitted by EM algorithm
> -----
>
> Mclust VEV (ellipsoidal, equal shape) model with 2 components:
>
> log-likelihood   n df       BIC       ICL
>      1317.177 335 37 2419.232 2372.163
>
> Clustering table:
>   1   2
> 267  68
```

Ce morceau de code ajuste un modèle de mélange gaussien avec deux groupes (G=2) en utilisant les données spécifiées. Ensuite, la fonction `summary()` nous fournit un aperçu détaillé des résultats du modèle. Cela inclut des informations telles que les paramètres estimés pour chaque groupe, les proportions de chaque groupe, et d'autres mesures importantes liées à la qualité du modèle. L'analyse de cette sortie nous permet de mieux comprendre la structure de nos données et les caractéristiques de chaque groupe identifié.

Incorporons les classifications des clusters dans notre dataframe initial. Pour ensuite afficher les premières lignes du dataframe ajusté fournissant un aperçu rapide des modifications.
